Warning: Subroutine MA21 performs functions which are adequately treated by routines in other standard subroutine libraries (for example, LAPACK). The use of this routine is not recommended, and it may be removed from future releases of this library.

1 SUMMARY

Given an \( n \) by \( n \) matrix \( A = \{a_{ij}\}_{n \times n} \) performs one or more of the following tasks.

(a) solves the system of linear algebraic equations

\[
\sum_{j=1}^{n} a_{ij} x_{j} = b_{i}, \quad i=1,2,...,n
\]

given the right-hand sides \( b_{i}, i=1,2,...,n \), and provides a re-entry facility for the rapid solution of further systems of equations which have the same elements \( a_{ij} \).

(b) computes the inverse matrix \( A^{-1} \) of \( A \).

(c) computes the value of the determinant of \( A \).

The subroutine will optionally perform iterative refinement in order to both improve the accuracy of the answer (solution or inverse) and provide error estimates based either on the precision of the computer or on user supplied accuracy information. An option for scaling the matrix is provided.

The method is basically Gaussian elimination with partial pivoting, implicit scaling and iterative refinement and applying small random perturbations in order to estimate errors, see S. Marlow and J.K. Reid, AERE R.6899.

2 HOW TO USE THE PACKAGE

2.1 Entries and argument lists

The entry points

To solve systems of linear equations as in § 1(a).

The single precision version

\[
\text{CALL MA21A(A,IA,N,B,W,E)}
\]

The double precision version

\[
\text{CALL MA21AD(A,IA,N,B,W,E)}
\]

To find inverse of matrix \( A \) in § 1(b).
The single precision version
CALL MA21B(A,IA,N,W,E)

The double precision version
CALL MA21BD(A,IA,N,W,E)

To find determinant of the matrix \( A \) as in § 1(c).

The single precision version
CALL MA21C(A,IA,N,DET,IDET,W)

The double precision version
CALL MA21CD(A,IA,N,DET,IDET,W)

Provided arguments \( A, IA, N, W \) have not been altered since a previous entry to \( MA21A/AD \) a new system with the same coefficients \( a_{ij} \) but different right-hand side elements \( b_i \) may be solved without repeating any of the work involved in the factorisation.

N.B. Iterative refinement \( E > 0 \) must not be requested unless the previous \( MA21A/AD \) entry also requested iterative refinement.

The single precision version
CALL MA21D(A,IA,N,B,W,E)

The double precision version
CALL MA21DD(A,IA,N,B,W,E)

The arguments

\( A \) is a REAL (DOUBLE PRECISION in the D version) two-dimensional array which contains the coefficients \( a_{ij} \) on entry. It is overwritten by its triangular factorisation on \( MA21A/AD, MA21C/CD \) entries and its inverse on \( MA21B/BD \) entry.

\( IA \) is an INTEGER variable set by the user to the first dimension of the array \( A \). It is not altered by the subroutine.

\( N \) is an INTEGER variable set to the number of equations (i.e. the order of the matrix \( A \) ). It is not altered by the subroutine.

\( B \) is a REAL (DOUBLE PRECISION in the D version) array of length at least \( N \) which must be set to the numbers \( b_1, b_2, ..., b_N \) and will contain the solution \( x_1, x_2, ..., x_N \) on exit.

\( W \) is a REAL (DOUBLE PRECISION in the D version) workspace array. The minimum length of this array is as follows.

(i) Iterative refinement required \( N \times (N+5) \) (\( MA21A/B/D, MA21AD/BD/DD \)).

(ii) No iterative refinement, with scaling \( 5 \times N \) (\( MA21A/B/C/D, MA21AD/BD/CD/DD \)).

(iii) No iterative refinement, no scaling \( N \) (\( MA21A/C/D, MA21AD/CD/DD \)) or \( 2 \times N \) (\( MA21B/BD \)).

If iterative refinement is required then parts of \( W \) may return error estimates on the solutions (see § 2.2); also \( W(4 \times N+I) \) will be set to contain \( B(I) \), \( I=1,N \) and \( W(5 \times N+I), I=1,N \times N \) will be set to contain the matrix \( A \). If scaling is in use then the subroutine sets \( W(2 \times N+I), W(3 \times N+I), I=1,N \) to the row and column scaling factors used.

\( E \) is a REAL (DOUBLE PRECISION in the D version) variable which must be set positive if iterative refinement is required and non-positive otherwise. On exit it will have one of the following values.

\( -2 \) Error condition in which execution could not continue. Any results should be treated as rubbish (see § 2.3).
Error condition found. Execution continued but results may be unreliable. (see § 2.3).

Successful entry without iterative refinement.

Successful entry with iterative refinement. It is set to an estimate of the size of the largest error in the solution ($x$ or $A^{-1}$) based on the assumption that all data was accurate to the full word length (see § 2.5 if this is not so).

$\text{DET}$, $\text{IDET}$ are $\text{REAL}$ ($\text{DOUBLE PRECISION}$ in the $\text{D}$ version) and $\text{INTEGER}$ variables respectively, and are set so that the determinant is held as $\text{DET} \times 16^{\text{IDET}}$. Usually $\text{IDET}=0$ but other values will be used if necessary to avoid overflow or underflow in $\text{DET}$.

For additional facilities see § 2.5.

2.2 Error estimates with iterative refinement in use.

If the rows and columns of $A$ have maximal elements which vary widely in size, then the single number $E$ may grossly over-estimate the errors in some of the components. In this case the user should examine the numbers $\tilde{W}(N+1), \ldots, \tilde{W}(2N)$ which give separate estimates for the errors in $x_1, x_2, \ldots, x_n$ ($\text{MA21A/D}$) or the numbers $\tilde{W}(J) \cdot \tilde{W}(I+N)$ which give estimates for the errors in $A_{ij}$ ($\text{MA21B}$).

N.B. If scaling has been inhibited by the use of $\text{JSCALE}$ (see § 2.5) then no estimates additional to that contained in $E$ are available and these components of $\tilde{W}$ are not set.

2.3 Error messages.

$\text{MA21A/AD}$ If it is found that a row or column (of $A$ or a pivot is small or zero then a diagnostic is printed (limited to one message per entry, later messages being suppressed). Execution is continued but iterative refinement is not attempted and $E$ is set to $-1$. In such cases the solution obtained is likely to be unreliable.

$\text{MA21B}$ If a row or column is found to be zero an error message is printed, $E$ set to $-2$ and a return is made to the calling program. If a pivot is found to be small the procedure for $\text{MA21A/D}$ is adopted.

$\text{MA21A/B/C/D}$ If $N \leq 0$ then $E$ is set to $-2$ before returning to calling program.

2.4 Method.

Unless requested otherwise (see § 2.5) the rows and columns of the matrix are implicitly scaled so that the pivots used are more likely to lead to low growth of roundoff errors. Gaussian elimination with row interchanges is used to factorise the given matrix.

When iterative refinement is requested, this is implicitly performed on the scaled system and continued until the largest change (in $x$ or $A^{-1}$) is greater than half its value on the previous iteration or is as small as the word-length allows. During this refinement pseudo-random changes are made to the data in accord with its specified accuracy (see § 2.5) and the size of the last maximal change is taken as an accuracy estimate. Finally the column scaling factors are multiplied by this estimate to give individual error estimates (see § 2.5) and $E$ is set to the largest of them.

2.5 Use of $\text{Common}$

The subroutine contains a common block called $\text{MA21E/ED}$ of the form:

The single precision version

$$\text{COMMON/MA21E/}$ $\text{LP, JSCALE, EA, EB}$$

The double precision version

$$\text{COMMON/MA21ED/}$ $\text{LP, JSCALE, EA, EB}$$

$\text{LP}$ is $\text{INTEGER}$ variable set initially to 6. It specifies the Fortran unit number for messages.

$\text{JSCALE}$ is $\text{INTEGER}$ variable set initially to 1. This indicates that scaling is done. If no scaling is required then the
value of JSIZE should be zero or negative. This option should only be used where speed is important.

\( E_A \) is REAL (DOUBLE PRECISION in the D version) variable. If \( E_A \geq 0 \) then it gives the fractional accuracy in the elements \( a_{ij} \) of \( A \). If \( E_A < 0 \) then \( |E_A| \) gives the absolute accuracy of the elements. This is defaulted to zero. \( E_A=0 \) indicates exact data.

\( E_B \) is REAL (DOUBLE PRECISION in the D version) variable. This is specified similarly to \( E_A \) and applies to the numbers \( b_1, b_2, \ldots, b_n \).

### 3 GENERAL INFORMATION

**Use of common:** uses a common block called MA21E/ED, see §2.5.

**Workspace:** passed as arguments, \( W \) see § 2.1.

**Other routines called directly:** calls FA01 and FD05.

**Input/output:** error messages, see LP in §2.5.
