

HSL

PACKAGE SPECIFICATION

### **1 SUMMARY**

This routine uses the **MINRES method to solve the**  $n \times n$  symmetric but possibly indefinite linear system Ax = b, optionally using preconditioning. If  $M = PP^T$  is the preconditioning matrix, the routine actually solves the preconditioned system

 $\bar{\mathbf{A}}\bar{\mathbf{x}}=\bar{\mathbf{b}},$ 

with  $\bar{\mathbf{A}} = \mathbf{P}\mathbf{A}\mathbf{P}^T$  and  $\bar{\mathbf{b}} = \mathbf{P}\mathbf{b}$  and recovers the solution  $\mathbf{x} = \mathbf{P}^T\bar{\mathbf{x}}$ . Reverse communication is used for preconditioning operations and matrix-vector products of the form  $\mathbf{A}\mathbf{z}$ .

ATTRIBUTES — Version: 1.1.0 (20 March 2023). Interfaces: Fortran Types: Real (single, double). Original date: April 2015. Origin: T. Rees, Rutherford Appleton Laboratory. Language: Fortran 95, plus allocatable dummy arguments and allocatable components of derived types.

## **2** HOW TO USE THE PACKAGE

### 2.1 Calling sequences

Access to the package requires a USE statement

Single precision version

USE HSL\_MI32\_single

Double precision version

USE HSL\_MI32\_double

If it is required to use both modules at the same time, then the derived types (Section 2.4) must be renamed in one of the USE statements.

The following procedures are available to the user:

- mi32\_minres is called repeatedly to solve the system using a reverse communication interface. On each return, the user must provide additional information and, if necessary, recall the subroutine.
- mi32\_finalize deallocates array components of the private derived data type (allocated by mi32\_minres), and should be called at the end of the solution process.

### 2.2 The derived data types

For each problem, the user must employ the derived types defined by the module to declare scalars of the types mi32\_keep, mi32\_control, and mi32\_info.

The following pseudo-code illustrates this.

```
use hsl_mi32_double
...
type(mi32_keep) :: keep
type(mi32_control) :: control
type(mi32_info) :: info
```

The components of mi32\_control and mi32\_info are explained in Section 2.4.1 and 2.4.2. The components of mi32\_keep are priavte and used to pass data between calls to the subroutines.

# HSL\_MI32

### 2.3 Argument lists and calling sequences

### 2.3.1 Integer, real and package types

INTEGER denotes default INTEGER.

REAL denotes default real if the single precision version is being used, and double precision real if the double precision version is being used.

We use the term **package type** to mean default real if the single precision version is being used, and double precision real for the double precision version.

### 2.3.2 The linear system solution subroutine

The linear system solution algorithm uses a reverse communication interface and must be called repeatedly (based on the value of action) as follows:

call mi32\_minres( action, n, X, V\_in, V\_out, keep, control, info )

action is a scalar INTENT(INOUT) argument of type INTEGER that is used for reverse communication. On the first call, action must be set to 1. On each subsequent return it specifies the action the user must perform as follows:

- <0 : An error has occured, see Section 2.5 for details.
  - 0 : MINRES has successfully converged to a solution that has been returned as the vector X.
  - 2 : The user must perform the preconditioning operation

$$\mathbf{y} := \mathbf{P}\mathbf{P}^T\mathbf{z},$$

where  $\mathbf{PP}^T$  is the preconditioning matrix, and recall mi32\_minres. The vector  $\mathbf{z}$  is available as the first n components of the array V\_out, and  $\mathbf{y}$  must be placed in V\_in. No argument except V\_in should be altered before recalling mi32\_minres.

3 : The user must perform the matrix-vector product

#### $\mathbf{y} := \mathbf{A}\mathbf{z}$

and recall mi32\_minres. The vector z is available as the first n components of the array V\_out, and y must be placed in V\_in. No argument except V\_in should be altered before recalling mi32\_minres.

- 4 : The user should test for convergence. This value will only occur when the user has opted to test convergence by setting control%own\_stopping\_rule to .TRUE.. If the user does not wish to test for convergence (we do not recommend the user tests for convergence each time action = 4 is returned) or if convergence has not been achieved, the user must recall mi32\_minres without changing any of the arguments.
- n is a scalar INTENT (IN) argument of type INTEGER that must be set to the number of unknowns, n. Restriction: n>0.
- X is an array INTENT (INOUT) argument of dimension n and package type that holds an estimate of the solution **x** of the linear system. On initial entry (action=1), X must contain an estimate of the solution. On exit, X contains the current best estimate of the solution.
- V\_in is an array INTENT(INOUT) argument of dimension n and package type that is used to pass information to mi32\_minres. The required content of the array is under the control of the parameter action (see above). On initial entry (action=1), V\_in must contain the residual Ax b.

V\_out is a one-dimensional POINTER array of package type that is used to pass information from mi32\_minres. The actual content of the array depends on the value of the parameter action (see above). Its allocation status and value must not be altered by the user.

keep is a scalar INTENT (INOUT) argument of type mi32\_keep. It is used to hold data about the system being solved.

control is a scalar INTENT (IN) argument of type mi32\_control.

```
info is a scalar INTENT (INOUT) argument of type mi32_info.
```

### **2.3.3** The termination subroutine

Pointer arrays holding private data are deallocated as follows:

call mi32\_finalize( keep )

keep is a scalar INTENT(INOUT) argument of type mi32\_keep exactly as for mi32\_minres. On exit, its array components will have been deallocated.

### 2.4 The derived types

### 2.4.1 The derived data type for holding control parameters

The derived data type mi32\_control is used to hold controlling data. The components, which are automatically given default values in the definition of the type, are:

- out is a scalar variable of type default INTEGER that holds the Fortran unit for diagnostic printing. Printing is suppressed if out < 0. The default is -1.
- error is a scalar variable of type default INTEGER that holds the Fortran unit for error messages. Printing of error messages is suppressed if error  $\leq 0$ . The default is 6.
- itmax is a scalar variable of type default INTEGER that holds the maximum number of iterations that will be allowed in mi32\_minres. If itmax is set to a negative number, it will be reset by mi32\_minres to n+1. The default is -1.
- conv\_test\_norm is a scalar variable of type default INTEGER that allows the user to select whether the algorithm tests for convergence in the *M*-norm (1) or the two-norm (2). If conv\_test\_norm = 2, then four additional vectors of length *n* will be stored. In general, the choice conv\_test\_norm = 2 will require a greater number of iterations, and each iteration will be more expensive as we perform an extra inner product and two additional vector additions per iteration. The default is 1. **Restriction:** conv\_test\_norm = 1 or 2.
- own\_stopping\_rule is a scalar variable of type default LOGICAL that is set .TRUE. if the user intends to provide the stopping rule and .FALSE. otherwise. The default is .false..
- precondition is a scalar variable of type default LOGICAL that is set .TRUE. if the user intends to provide a preconditioner and .FALSE. otherwise. The default is .true..
- stop\_relative and stop\_absolute are scalar variables of package type that holds the relative and absolute convergence tolerances (see Section 4). If own\_stopping\_rule is .TRUE., stop\_relative and stop\_absolute are not accessed by MI32. Otherwise, the computed solution x is accepted by mi32\_minres if  $||Ax b||_{\star}$  is less than or equal to max( $||Ax_0 b||_{\star} *$  stop\_relative, stop\_absolute), where  $x_0$  is the initial estimate of the solution.  $|| \cdot ||_{\star}$  denotes the norm selected by the control parameter conv\_test\_norm. The default values are stop\_relative = SQRT( EPSILON ) and stop\_absolute = 0.0.

# HSL\_MI32

### 2.4.2 The derived data type for informational parameters

The derived data type mi32\_info is used to hold parameters that give information about the progress and needs of the algorithm. The components of mi32\_info are:

rnorm is a scalar variable of package type that holds the two norm of the residual,  $||Ax - b||_{\star}$ , where  $|| \cdot ||_{\star}$  denotes the norm chosen by the control parameter control\_test\_norm.

iter is a scalar variable of type default INTEGER that holds the current iteration count.

st is a scalar variable of type default INTEGER that gives the status of the most recent array allocation.

### 2.5 Warning and error messages

A negative value of action on exit from mi32\_minres indicates that an error has occurred. No further calls should be made until the problem has been resolved. Possible values are:

- -1. The input parameter n is not positive.
- -2. More than control%itmax iterations have been performed without obtaining convergence.
- -3. The matrix **A** appears to be singular and the system inconsistent.
- -4. An array allocation has failed. A message indicating the offending array is written on unit control%error and the returned allocation status is given by info%st.
- -5. A value of control%conv\_test\_norm other than 1 or 2 has been supplied.

### 2.6 Information printed

If control%out is positive, information about the progress of the algorithm will be printed on unit control%out. A one-line summary of each iteration will be given containing the iteration number, the norm of the residual, the latest diagonal and off-diagonal elements in the Lanczos tridiagonal matrix (see Section 2.4.2) and a flag indicating the pivot type used when factorizing this matrix.

## **3** GENERAL INFORMATION

**Input/output:** Output is under control of the arguments control%error and control%out.

**Restrictions:** n > 0.

## 4 METHOD

The method is iterative. Starting with the vector  $(\mathbf{A}\mathbf{x}_0 - \mathbf{b})/||P^T(\mathbf{A}\mathbf{x}_0 - \mathbf{b})||_2$ , a matrix of Lanczos vectors is built one column at a time so that the *k*-th column is generated during iteration *k*. The resulting  $n \times k$  matrix  $\mathbf{Q}_k$  has the property that

$$\mathbf{A}\mathbf{Q}_{k}=\mathbf{Q}_{k}\mathbf{T}_{k}+\gamma_{k+1}\begin{bmatrix}\mathbf{0}&\cdots&\mathbf{0}&\mathbf{v}_{k+1}\end{bmatrix},$$

or, equivalently,  $\mathbf{Q}_k^T \mathbf{A} \mathbf{Q}_k = \mathbf{T}_k$ , where  $T_k$  is tridiagonal. An approximation to the required solution may then be expressed formally as  $\mathbf{x}_{k+1} = \mathbf{x}_0 - \mathbf{Q}_k \mathbf{y}_k$ , where

$$\mathbf{y}_k = \arg\min \|\|\mathbf{r}_0\|_2 \mathbf{e}_1 - \widehat{\mathbf{T}}_{k+1}\|_2.$$

Here  $\widehat{\mathbf{T}}_{k+1} \in \mathbb{R}^{(k+1) \times k}$  is formed by appending the row  $\begin{bmatrix} 0 & \cdots & 0 & \gamma_{k+1} \end{bmatrix}$  to  $\mathbf{T}_k$ , and  $\mathbf{e}_1$  is the first unit vector. The MINRES algorithm implicitly solves this least squares problem using Givens rotations.

At the *k*th iteration MINRES finds the vector  $\mathbf{x}_k \in P(\mathbf{x}_0 + \text{span}\{AM\mathbf{r}_0, (AM)^2\mathbf{r}_0, \dots, (AM)^{k-1}\mathbf{r}_0\})$  that minimizes  $\|A\mathbf{x}_k - \mathbf{b}\|_M$ . If MINRES is used without a preconditioner we therefore have that the solution in the Krylov subspace with the minimal residual in the two-norm is found.

The aim of preconditioning is to accelerate the convergence of the method by clustering the eigenvalues of the preconditioned matrix  $\bar{\mathbf{A}}$  around a small number of distinct values. If  $\mathbf{A}$  is positive definite, this is often achieved by choosing  $\mathbf{PP}^T \approx \mathbf{A}^{-1}$ . When  $\mathbf{A}$  is indefinite, such a choice will not be possible, and the best that can be hoped for is that the eigenvalues of  $\bar{\mathbf{A}}$  cluster around one positive and one negative value.
